

x1814 - Change Host

Version 0

Change Host

[0] `getHostInfo()` → `nbHost`, `currHost`, `flags`
[1] `setCurrentHost(currHost)`
[2] `getCookies()` → `cookie`
[3] `setCookie(host, cookie)`

Overview

In case of a device having several RF channels, this feature allows to select explicitly a particular channel / host.

Every channel is connectable to a different host whatever the RF protocol (Unifying, BLE, Bolt ...)

Functions and Events

[0] `getHostInfo()` → `nbHost`, `currHost`, `flags`

Get info on the host implementation

Parameters

none

Returns

nbHost

The number of hosts / Rf channels

currHost

The current host index, starting from 0. If we have `nbHost`, the current host can be `0...nbHost - 1`

flags

bit 0 - enhanced host switch on/off → Currently the default value of "flags" is "0" (i.e inactive)
FW tries to connect the specified host

If no success, it will try to connect any host having `cookie != 0` and starting from the lowest host (the original host and the specified host are excluded - so for Cala / Talise remains one possibility)

If no success, FW reconnects the original host

Table 1. `getHostInfo()` response packet format

| byte \ bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|----------|----------|----------|----------|----------|----------|----------|------------|
| 0 | nbHost | | | | | | | |
| 1 | currHost | | | | | | | |
| 2 | flags | | | | | | | |
| | reserved | reserved | reserved | reserved | reserved | reserved | reserved | ehs on/off |
| 3..15 | reserved | | | | | | | |

Errors

none

[1] setCurrentHost(currHost)

Set the current host; no return, since, if successful, the device will most probably reset

Parameters

currHost

Index of the new host to select

Table 2. *setCurrentHost()* request packet format

| byte \ bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|----------|---|---|---|---|---|---|---|
| 0 | currHost | | | | | | | |
| 1..15 | reserved | | | | | | | |

Returns

none

Errors

none

[2] getCookies() → cookie

Get the data byte for each host

Parameters

none

Returns

Cookie

For every host, the SW has the possibility to read / write a personal data byte ("Cookie"), that will be stored permanently in the device's non volatile memory.

It can be used for example to determine if a given host has a specific SW installed

| | |
|------|---|
| NOTE | SW can write any value, however: |
| | 1) The cookies are all zero for an OOB device |
| | 2) When a new host is connected, FW clears (= 0) the corresponding cookie |

Table 3. *getCookies() response packet format*

| byte \ bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------------------|--------------------|---|---|---|---|---|---|---|
| 0 | cookie[0] | | | | | | | |
| 1 | cookie[1] | | | | | | | |
| ... | ... | | | | | | | |
| cookie[nbHost - 1] | cookie[nbHost - 1] | | | | | | | |
| nbHost..15 | reserved | | | | | | | |

Errors

none

[3] setCookie(host, cookie)

Write the specified cookie

Parameters

host

Channel / host index

cookie

The value to write

Table 4. *setCookie() request packet format*

| byte \ bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|----------|---|---|---|---|---|---|---|
| 0 | host | | | | | | | |
| 1 | cookie | | | | | | | |
| 2..15 | reserved | | | | | | | |

Returns

none

Errors

InvalidArgument (2) Invalid host index
